# Joint probability distribution

- **Joint probability distribution** for a set of r.v.s (random variables) gives the probability of every atomic event on those r.v.s (i.e., every sample point)

$P(Cavity, Weather)$  is a  $2 \times 4$  matrix of values

$$\begin{pmatrix} 0.144 & 0.02 & 0.016 & 0.02 \\ 0.576 & 0.08 & 0.064 & 0.08 \end{pmatrix}$$

which can be interpreted as

	$W. = sunny$	$W. = rain$	$W. = cloudy$	$W. = snow$
$Cavity = true$	0.144	0.02	0.016	0.02
$Cavity = false$	0.576	0.08	0.064	0.08

- **Every** question about a domain can be answered by the joint distribution because every event is a sum of sample points.
- E.g.,  $P(Cavity = true \text{ AND } Weather \neq cloudy)$

# Inference by enumeration

*(Paramount Pictures)*

# Inference by enumeration

- Example of a joint distribution with **three** variables (catch is something the doctor can test):

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- For any proposition  $\phi$ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega: \omega \models \phi} P(\omega)$$

# Inference by enumeration

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- For any proposition  $\phi$ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega: \omega \models \phi} P(\omega)$$

$$\begin{aligned} P(\text{toothache}) &= 0.108 + 0.012 + 0.016 + 0.064 \\ &= 0.2 \end{aligned}$$

# Inference by enumeration

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- For any proposition  $\phi$ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega: \omega \models \phi} P(\omega)$$

$$\begin{aligned} P(\text{cavity} \vee \text{toothache}) &= 0.108 + 0.012 + 0.072 \\ &\quad + 0.008 + 0.016 + 0.064 \\ &= 0.28 \end{aligned}$$

## Your turn

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- Calculate  $Pr(\text{toothache} \wedge \text{cavity})$ .
- I encourage you to use the KEATS forum to compare your answers!

## Your turn

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- Calculate  $Pr(cavity \mid toothache)$ .
- I encourage you to use the KEATS forum to compare your answers!

# Inference by enumeration

- Can also compute conditional probabilities:

$$\begin{aligned}P(\neg cavity | toothache) &= \frac{P(\neg cavity \wedge toothache)}{P(toothache)} \\&= \frac{0.016 + 0.064}{0.108 + 0.012 + 0.016 + 0.064} \\&= 0.4\end{aligned}$$

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

$$\frac{P(\neg cavity \wedge toothache)}{P(toothache)}$$

# Notation

- Notation for conditional distributions:

$$\mathbf{P}(\textit{Cavity}|\textit{toothache})$$

The outcome is a 2-dimensional vector (and so is Cavity). Write it down and compare!

# Conditional probability

- Conditional or posterior probabilities

$$P(\text{cavity}|\text{toothache}) = 0.6$$

given that *toothache* **is all I know**

Recall, for convenience we write *cavity* for  $Cavity = true$  and *toothache* for  $Toothache = true$ .

# Conditional probability

- Conditional or posterior probabilities

$$P(\text{cavity}|\text{toothache}) = 0.6$$

given that *toothache* **is all I know**

- If we know more, e.g., *cavity* is also given, then we have

$$P(\text{cavity}|\text{toothache}, \text{cavity}) = 1$$

Note: the less specific belief (toothache) **remains valid** after more evidence arrives, but is not always **useful**

# Conditional probability

- Conditional or posterior probabilities

$$P(\text{cavity}|\text{toothache}) = 0.6$$

given that *toothache* **is all I know**

- If we know more, e.g., *cavity* is also given, then we have

$$P(\text{cavity}|\text{toothache}, \text{cavity}) = 1$$

Note: the less specific belief (toothache) **remains valid** after more evidence arrives, but is not always **useful**

- New evidence may be irrelevant, allowing simplification

$$P(\text{cavity}|\text{toothache}, \text{your curtains are red}) = P(\text{cavity}|\text{toothache}) = 0.6$$

- This kind of inference, sanctioned by domain knowledge, is crucial.

# Conditional probability

- Definition of conditional probability:

$$P(a|b) = \frac{P(a \wedge b)}{P(b)} \text{ if } P(b) > 0$$

- **Product rule** gives an alternative formulation:

$$P(a \wedge b) = P(a|b)P(b) = P(b|a)P(a)$$

- A general version holds for joint distributions,

$$\mathbf{P}(\textit{Weather}, \textit{Cavity}) = \mathbf{P}(\textit{Weather}|\textit{Cavity}) \odot \mathbf{P}(\textit{Cavity})$$

(View as a  $4 \cdot 2 = 8$  set of equations, **not** matrix multiplication - unless you know exactly what you're doing and you model everything correctly)

# Chain rule

- **Chain rule** is derived by successive application of product rule. Concrete example:

$$\begin{aligned}P(a, b, c) &= P(a, b)P(c|b, a) \\ &= P(a)P(b|a)P(c|b, a)\end{aligned}$$

- In general,

$$\begin{aligned}\mathbf{P}(X_1, \dots, X_n) &= \mathbf{P}(X_1, \dots, X_{n-1})\mathbf{P}(X_n|X_1, \dots, X_{n-1}) \\ &= \mathbf{P}(X_1, \dots, X_{n-2})\mathbf{P}(X_{n-1}|X_1, \dots, X_{n-2})\mathbf{P}(X_n|X_1, \dots, X_{n-1}) \\ &= \dots \\ &= \prod_{i=1}^n \mathbf{P}(X_i|X_1, \dots, X_{i-1})\end{aligned}$$

# Normalisation

We can use  $\alpha = 1/P(\text{toothache})$  to normalise (we don't need to calculate it!)

$$\begin{aligned}\mathbf{P}(\text{Cavity}|\text{toothache}) &= \alpha \mathbf{P}(\text{Cavity}, \text{toothache}) \\ &= \alpha [\mathbf{P}(\text{Cavity}, \text{toothache}, \text{catch}) + \mathbf{P}(\text{Cavity}, \text{toothache}, \neg \text{catch})] \\ &= \alpha \left[ \begin{pmatrix} 0.108 \\ 0.016 \end{pmatrix} + \begin{pmatrix} 0.012 \\ 0.064 \end{pmatrix} \right] = \alpha \begin{pmatrix} 0.12, \\ 0.08 \end{pmatrix} = \begin{pmatrix} 0.6, \\ 0.4 \end{pmatrix}\end{aligned}$$

	<i>toothache</i>		$\neg$ <i>toothache</i>	
	<i>catch</i>	$\neg$ <i>catch</i>	<i>catch</i>	$\neg$ <i>catch</i>
<i>cavity</i>	<b>.108</b>	<b>.012</b>	<b>.072</b>	<b>.008</b>
$\neg$ <i>cavity</i>	<b>.016</b>	<b>.064</b>	<b>.144</b>	<b>.576</b>

- Green boxes show step in calculation, not the desired outcome

# General version

- Let  $\mathbf{X}$  be all the variables.
- Typically, we want the posterior joint distribution of the **query variables**  $\mathbf{Y}$  given specific values  $\mathbf{e}$  for the **evidence variables**  $\mathbf{E}$
- Let the **hidden variables** be  $\mathbf{H} = \mathbf{X} - \mathbf{Y} - \mathbf{E}$

# General version

- Then the required summation of joint entries is done by **summing out** the hidden variables:

$$\begin{aligned}\mathbf{P}(\mathbf{Y}|\mathbf{E} = e) &= \alpha \mathbf{P}(\mathbf{Y}, \mathbf{E} = e) \\ &= \alpha \sum_h \mathbf{P}(\mathbf{Y}, \mathbf{E} = e, \mathbf{H} = h)\end{aligned}$$

- The terms in the summation are joint entries because  $\mathbf{Y}$ ,  $\mathbf{E}$ , and  $\mathbf{H}$  together exhaust the set of random variables
